1. Executive Summary

Advertising platforms such as Meta and Google routinely over-report the sales they generate. They double-count customers who saw ads on both platforms and claim credit for purchases that would have happened anyway. Decisions made on those inflated numbers waste budget.

This dashboard is a single marketing command center. It pulls data from **Meta Ads**, **Google Ads**, **Shopify** and **Shiprocket**, cross-checks them, and subtracts returns and cancellations. The result is the **actual cash collected (True Revenue)** plus clear daily guidance on which campaigns to scale, cut, or hold. Every figure is computed on the backend in Python and stored to a database on each sync.

2. How the System Simplifies Your Decisions

A. Reconciled 'True' Revenue — the single source of truth. We take Shopify sales, subtract customer refunds, then cross-check Shiprocket to remove cancelled orders and COD parcels returned unpaid (Return-to-Origin). What remains is real business cash flow — not what the ad managers claim.

B. Two attribution windows, side by side. Customers deliberate before buying, so every campaign is shown two ways:

- **1-Day Click:** sales within 24 hours — best for fast daily tweaks.
- **7-Day Click:** delayed sales — reveals slow-converting winners.

C. Daily briefing (AI layer). A plain-English summary of what improved, what got worse and what is stuck (e.g. near stock-outs), with explicit actions: **Scale** winners, **Cut** losers, or **Hold** campaigns that convert on a delay.

3. Architecture at a Glance

4. Workflow Breakdown

Stage	What happens	What it gives you
1. Sync	Fetches metrics automatically (daily) or via the Refresh button, into the database.	No manual copy-paste; every source stays current with an audit trail.
2. Reconcile	Shopify revenue is cross-checked against Shiprocket delivery statuses.	Filters out cancellations and RTOs, leaving only cash actually collected.

3. Evaluate	Compares 1-day vs 7-day ROAS against tunable thresholds.	Prevents premature pausing of slow-converting ads; protects ad yield.
4. Display	Renders calculated stats and a ranked action list on the dashboard.	A five-minute plain-English summary to start the workday.

5. Running Live — From Demo to Real Accounts

Each source runs in one of three modes, chosen independently:

- **Real API** — used automatically once real keys are in the `.env` file.
- **Demo-live** — with no keys, the system makes real calls to a free public API so the numbers move and the dashboard runs 'live' for testing.
- **Sample** — fixed demo data when live mode is turned off.

Going live is a configuration change, not a code change. The real API integration for all four connectors is already written; replacing the placeholder values in `.env` switches each source to its live account on the next restart. Storage points at PostgreSQL by setting `DATABASE_URL`; without it, a local database is used automatically.
